## Executive Summary

This Report has been written for the European Commission, DG TAXUD, for the project TAXUD/2019/AO-14, “Study and Reports on the VAT Gap in the EU-28 Member States”, and is a follow-up to the seven reports published between 2013 and 2019.

This Study contains Value Added Tax (VAT) Gap estimates for 2018, fast estimates using a simplified methodology for 2019, the year immediately preceding the analysis, and includes revised estimates for 2014-2017. It also includes the updated and extended results of the econometric analysis of VAT Gap determinants initiated and initially reported in the 2018 Report (Poniatowski et al., 2018). As a novelty, the econometric analysis to forecast potential impacts of the coronavirus crisis and resulting recession on the evolution of the VAT Gap in 2020 is reported.

In 2018, most European Union (EU) Member States (MS) saw a slight decrease in the pace of gross domestic product (GDP) growth, but the economic conditions for increasing tax compliance remained favourable. We estimate that the VAT total tax liability (VTTL) in 2018 increased by 3.6 percent whereas VAT revenue increased by 4.2 percent, leading to a decline in the VAT Gap in both relative and nominal terms. In relative terms, the EU-wide Gap dropped to 11 percent and EUR 140 billion. Fast estimates show that the VAT Gap will likely continue to decline in 2019.

Of the EU-28, the smallest Gaps were observed in Sweden (0.7 percent), Croatia (3.5 percent), and Finland (3.6 percent), the largest – in Romania (33.8 percent), Greece (30.1 percent), and Lithuania (25.9 percent). Overall, half of the EU-28 MS recorded a Gap above 9.2 percent. In nominal terms, the largest Gaps were recorded in Italy (EUR 35.4 billion), the United Kingdom (EUR 23.5 billion), and Germany (EUR 22 billion).

The Policy Gap and its components remained stable. For the EU overall, the average Policy Gap level was 44.24 percent. Of this, in 2018, 10.07 percentage points were due to the application of various reduced and super-reduced rates (the Rate Gap) and 34.17 were due to the application of exemptions without the right to deduct.

The results of the econometric analysis show that the VAT Gap is influenced by a group of factors relating to the current economic conditions, institutional environment, and economic structure as well as to the measures and actions of tax administrations. Out of a broad set of tested variables, GDP growth and general government balance appeared to explain a substantial set of VAT Gap variation across time and countries. Within the control of tax administrations, share of IT expenditure proved to have the highest statistical significance in explaining the size of the VAT Gap. In addition, the VAT Gap appeared to be inter-related with the values of risky imports of goods, indicating the role of fraud in driving the overall share of the VAT Gap.

Since the COVID-19 recession will likely have a dire impact on the EU economies, the VAT Gap in 2020 is forecasted to increase. If the EU economy contracts by 7.4 percent in 2020 and the general government deficit jumps as forecasted in the Spring Forecast of the European Commission, the Gap could increase by 4.1 percentage points year-over-year up to 13.7 percent and EUR 164 billion in 2020. The hike in 2020 could be more pronounced than the gradual decrease of the Gap observed over the three preceding years. Moreover, a return to the VAT Gap levels observed in 2018 and 2019 will take time and require significant action from tax administrations.

## Introduction

This Report presents the findings of the 2020 “Study to quantify the VAT Gap in the EU Member States”, which is the seventh publication following the original Study conducted by Barbone et al. in 2013<sup>1</sup>.

We present Value Added Tax (VAT) Gap estimates for 2018, fast estimates using a simplified methodology for 2019, the year immediately preceding the analysis, and include revised estimates for 2014-2017<sup>2</sup>. We also include updated and extended results of the econometric analysis of VAT Gap determinants initiated and initially reported in the 2018 Report (Poniatowski et al., 2018). As a novelty, we operationalise the econometric analysis to forecast potential impacts of the coronavirus crisis and resulting recession on the evolution of the VAT Gap in 2020 and 2021.

The VAT Gap, which is addressed in detail by this Report shall be understood as the Compliance Gap. It is the difference between the expected and actual VAT revenues and represents more than just fraud and evasion and their associated policy measures. The VAT Gap also covers VAT lost due to, for example, insolvencies, bankruptcies, administrative errors, and legal tax optimisation. It is defined as the difference between the amount of VAT collected and the VAT Total Tax Liability (VTTL) – namely, the tax liability according to tax law. The VAT Gap can be expressed in absolute or relative terms, commonly as a ratio of the VTTL or gross domestic product (GDP). In this Report, we refer to the VAT Gap as the ratio of the VTTL.

In addition to the analysis of the Compliance Gap, this Report also updates the Policy Gap estimates from 2018 as well as the contribution that reduced rates and exemptions made to these theoretical VAT revenue losses.

The structure of this Report builds on the previous publications. Chapter 1 presents the main economic and policy factors that affected European Union (EU) Member States (MS) during the course of 2018. It also includes a decomposition of the change in VAT revenues. The overall results are presented and briefly described in Chapter 2. Chapter 3 provides detailed results and outlines trends for individual countries coupled with analytical insights. In Chapter 4, we examine the Policy Gap and the contribution that VAT reduced rates and exemptions have made to this Gap. Chapter 5 is devoted to the econometric analysis. It provides an overview of the literature, highlights the most important novelties introduced with this update, and discusses and visualises the results which are complemented by a robustness check. The final chapter presents the impact of the coronavirus recession on the evolution of the VAT Gap. Annex A contains the methodological considerations underlying all components of the

---

<sup>1</sup> The first study of the VAT Gap in the EU was conducted by Reckon (2009); however, due to differences in methodology, it cannot be directly compared to these latter studies.

<sup>2</sup> The estimates for 2019 are referred to as “fast” since they use different method described in Section d in Annex A and could be associated with larger estimation error.

analysis. Annex B provides statistical data and a set of comparative tables, whereas Annex C provides additional graphs.

## 1. Background: Economic and Policy Context in 2018

### a. Economic Conditions in the EU during 2018

In 2018, most EU MS saw a moderate decrease in the pace of GDP growth. Overall, growth of the EU economy fell from 2.5 percent in 2017 down to 2.0 percent in 2018 in real terms. Positive economic tailwinds provided particularly good conditions for an increase in VAT collections in Ireland (GDP growth of 8.2 percent), Poland (5.3 percent), and Hungary (5.1 percent). The lowest GDP growth rates were observed in Italy (0.8 percent) and the United Kingdom (1.5 percent).

In nominal terms, GDP increased by 3.3 percent and consumer prices by 1.9 percent. Final consumption, which is the core of the VAT base (68 percent of the VTTL in 2018), increased by 3.1 percent in total. Investment in gross fixed capital formation (GFCF, which made up 14 percent of the VTTL in 2018) increased by 4.2 percentage points for the entire EU.

The change in GFCF was volatile across countries and varied from -18.7 percent in Ireland to 24.4 percent in Hungary. Due to the volatility and frequent revisions of GFCF figures by Statistical Offices, GFCF is the main source of VAT Gap revisions. Whenever new information on the actual investment figures of exempt sectors becomes available, the estimates of VAT Gap are revised backwards.

General government budgets and the labour markets remained relatively sound. The average general government balance amounted to -0.7 percent with half of EU MS observing a nominal surplus. The unemployment rate fell in nearly all EU MS and by -0.9 percent on average.

**Table 1.1. Real and Nominal Growth in the EU-28 in 2018 (in national currencies [NAC])**

Member State	Real GDP Growth (%)	General Government Balance (%)	Change in Unemployment Rate (pp)	Nominal Growth (%)

## b. VAT Regime Changes

2018 was another stable year in terms of both EU-wide and country-specific changes affecting the VTTL.

The temporary measure of the Mini One Stop Shop (MOSS) retention fee, which is the revenue retained in the country of origin of service providers obliged to pay VAT in the country of residence of their customers, was maintained in 2018 at the level of 15 percent. For this reason, the rule for estimating the VTTL of electronic services remained unchanged.

As for country-specific changes, only one MS implemented significant changes to the structure of its VAT rates in 2018. As of January 2018, Latvia introduced a super-reduced rate of 5 percent applicable to a range of common vegetables and fruits. There were also a few examples of the reclassification of rates applicable to certain products. Among those, Lithuania applied a reduced rate of 9 percent on accommodation services (down from 21 percent). Similarly, starting from November, Romania applied a reduced rate of 5 percent to accommodation, restaurants, and catering services. In Hungary, the rate applicable to Internet access services was reduced from 18 percent to 5 percent.

Overall, the average effective rate remained unchanged compared to 2017 and accounted for 12 percent<sup>3</sup>.

**Table 1.2. VAT Rate Structure as of 31 December 2017 and Changes during 2018 (%)**

Member State	Standard Rate (SR)	Reduced Rate(s) (RR)	Super-Reduced Rate	Parking Rate	Changes during 2018	Effective Rate <sup>4</sup>
Belgium	21	6 / 12	-	12		10.1
Bulgaria	20	9	-	-		14.0
Czechia	21	10 / 15		-		12.6
Denmark	25	-	-	-		14.9
Germany	19	7	-	-		10.6
Estonia	20	9	-	-		12.9
Ireland	23	9 / 13.5	4.8	13.5		12.3
Greece	24	6 / 13	-	-		13.1
Spain	21	10	4	-		8.8
France	19.6	5.5 / 10	2.1	-		9.6
Croatia	25	5 / 13	-	-		16.4
Italy	22	10	4 / 5	-		10.2
Cyprus	19	5 / 9	-	-		10.5

<sup>3</sup> Changes in the effective rate compared to the 2017 Report also result from the revision of the VTTL estimates and the statistical data underlying the estimates.

<sup>4</sup> The effective rate is the ratio of the VTTL and the tax base. See methodological considerations in Section c in Annex A.

Member State	Standard Rate (SR)	Reduced Rate(s) (RR)	Super-Reduced Rate	Parking Rate	Changes during 2018	Effective Rate
Latvia	21	12	5	-	Super-Reduced Rate introduced (5%)	11.8
Lithuania	21	5 / 9	-	-		13.6
Luxembourg	17	8	3	14		12.2
Hungary	27	5 / 18	-	-		14.8
Malta	18	5 / 7	-	-		12.1
Netherlands	21	6	-	-		10.0
Austria	20	10 / 13	-	12		11.3

### c. Sources of Change in VAT Revenue Components

The value of the actual VAT revenue can be decomposed into components, which is helpful in understanding the underlying sources of its evolution. Since revenue is a product of the VTTL and the compliance ratio<sup>5</sup>, VAT collection could be expressed as:

$$\text{Actual Revenue} = \text{VTTL} \times \text{Compliance Ratio},$$

where Compliance Ratio is:  $1 - \text{VAT Gap} (\%)$ .

As the VTTL is a product of the base and the effective rate, the actual revenue could be further decomposed and expressed as:

$$\text{Actual Revenue} = \text{Net Base} \times \text{Effective Rate} \times \text{Compliance Ratio},$$

where Effective Rate is the ratio of the theoretical VTTL to the Net Base. The Net Base (which is the sum of the final consumption and investment by households, non-profit institutions serving households [NPISH], and government), in turn, is calculated as the difference between the Gross Base, which includes VAT, and the VAT revenues actually collected.

<sup>5</sup> In other words, VAT collection efficiency.

Table 1.3 and Figure 1.1 present the decomposition of the total changes in nominal VAT revenues into these three components: change in net taxable base, change in the effective rate applied to the base, and change in the compliance ratio.

**Table 1.3. Change in VAT Revenue Components (2018 over 2017)**

Member State	Change in Revenue	Change in the VTTL		Change in Compliance	
		Change in Base	Change in Effective Rate		
Belgium	4.3%	3.1%	3.6%	-0.5%	1.2%
Bulgaria	9.3%	7.5%	8.0%	-0.4%	1.7%
Czechia	6.5%	6.6%	7.8%	-1.1%	-0.1%
Denmark	4.3%	3.1%	3.2%	0.0%	1.2%
Germany	3.8%	3.6%	3.3%	0.2%	0.2%
Estonia	8.5%	7.5%	8.8%	-1.2%	0.9%

**Figure 1.1. Change in VAT Revenue Components (2018 over 2017, %)**

Source: own calculations.

As depicted by Table 1.3 and Figure 1.1 and highlighted in the preceding section, the growth of the base was the main driver of VAT revenue growth in 2018. An increase in the base contributed to approximately 78 percent of the total VAT revenue growth in the EU. The effect of increased compliance contributed to approximately 10 percent of the growth, which translated to 0.4 percent of the overall VAT revenue.

For the vast majority of EU MS, both the tax base and compliance effect were positive. In five countries, namely Hungary, Romania, Latvia, Malta, and Poland, the overall effect of the increase in the tax base and compliance exceeded 10 percent of VAT revenue.

## 2. The VAT Gap in 2018

The estimates of the VAT Gap presented in this section were derived using the same methodology as in the previously cited VAT Gap Studies. The VAT Gap is defined as the difference between the VTTL and the amount of VAT actually collected over the same period. We compute the VTTL using a top-down “consumption-side” approach by deriving the expected VAT liability from the observed national accounts data, such as supply and use tables (SUT). For this reason, the methodology used in this Study relies on the availability and quality of SUT data, which vary country to country.

The VAT liability is estimated for final household, government, and NPISH expenditures; non-deductible VAT from the intermediate consumption of exempt industries; and VAT from the GFCF of exempt sectors. We also account for country-specific tax regulations, such as exemptions for small businesses under the VAT thresholds (if applicable); non-deductible business expenditures on food, drinks, and accommodation; and restrictions to deduct VAT on leased cars, among others. The precise formula is given in Section c in Annex A.

The results presented in this report are not fully comparable with the results presented in the earlier Reports, as each year some figures are revised backwards. The main source of the revisions are the updates of national accounts and revenue figures compiled by Member States. Moreover, in the course of our computations, some expenditure and investment figures that are not available for the most recent years are estimated. Thus, whenever actual national accounts data is published or new information on taxable investment becomes available, VAT Gap estimates need to be revised. A detailed discussion on the sources of the revisions is presented in Section a in Annex A.

In nominal terms, in 2018, the VTTL and VAT revenue amounted to EUR 1,272 billion and EUR 1,132 billion, respectively. Compared to 2017, VAT revenue increased by 4.2 percent whereas the VTTL increased by 3.6 percent, leading to decline in the VAT Gap in both relative and nominal terms. In relative terms, the EU-wide Gap dropped to 11 percent. Fast estimates show that the VAT Gap will likely continue to decline in 2019 and could fall below EUR 130 billion and 10 percent of the VTTL<sup>6</sup>.

**Figure 2.1. Evolution of the VAT Gap in the EU, 2014-2018 and Fast Estimate for 2019**

Source: own calculations.

The smallest Gaps were observed in Sweden (0.7 percent), Croatia (3.5 percent), and Finland (3.6 percent), the largest – in Romania (33.8 percent), Greece (30.1 percent), and Lithuania (25.9 percent). Overall, half of the EU-28 MS recorded a Gap above 9.2 percent (see Figure 2.2 and Table 2.1). In nominal terms, the largest Gaps were recorded in Italy (EUR 35.4 billion), the United Kingdom (EUR 23.5 billion), and Germany (EUR 22.1 billion).

<sup>6</sup> As discussed in Section d in Annex A fast estimates use a simplified methodology and their accuracy is lower.

**Figure 2.2. VAT Gap as a percent of the VTTL in EU-28 Member States, 2018 and 2017**

Source: own calculations.

The rank of MS with respect to the relative size of the Gap remained relatively stable, with the largest changes in position observed for Hungary and Latvia (improvement by eight and six positions, respectively). The VAT Gap share decreased in 21 countries. The most significant decreases in the VAT Gap occurred in Hungary (-5.1 percentage points), Latvia (-4.4 percentage points), and Poland (-4.3 percentage points), whereas the biggest increases were observed for Luxembourg (+2.5 percentage points), Lithuania (+0.8 percentage points), and Austria (+0.5 percentage points) (see Figure 2.3).

### Highlights

- In 2018, the VAT Gap accounted for 10.4 percent of the VTTL (a decline of 1.1 percentage points compared to 2017).
- The VAT revenue reported by Eurostat contains *VAT assessed but unlikely to be collected*. This component was removed from the reference figures to ensure comparability with other EU MS.

### Highlights

- The VAT Gap in Bulgaria in 2018 amounted to 10.8 percent, which is about the EU total.
- After a considerable improvement in 2016, the VAT Gap in Bulgaria has remained stable and is expected to remain so in 2019 based on fast estimates.

### Highlights

- The VAT Gap in Czechia as a percent of the VTTL remained nearly unchanged in 2018 as compared to 2017.
- The revenue was amended to more accurately reflect tax accrued to taxation period on the basis of information received from the Tax Authorities. For 2018, VAT revenue reported by Eurostat was revised upwards by CZK 3.8 billion.

### Highlights

- Over the period 2015-2018, the VAT Gap in Germany has remained nearly constant, amounting to ca. 9 percent of the VTTL.
- The estimates for Germany were revised backwards due to an improved methodology for imputing missing and confidential values in Eurostat's SUT.

Table 3.6. Estonia: VAT Revenue, VTTL, Composition of VTTL, and VAT Gap, 2014-2018 (EUR million)

#### Highlights

- Over the period 2015-2018, the VAT Gap in Estonia has remained stable in the range between 5 and 6 percent of the VTTL.
- No substantial change in the size of the VAT Gap is expected based on fast estimates.

Table 3.7. Ireland: VAT Revenue, VTTL, Composition of VTTL, and VAT Gap, 2014-2018 (EUR million)

### Highlights

- The estimates for Ireland were revised backwards due to an improved methodology for imputing missing and confidential values in Eurostat's SUT.
- The VAT Gap in Ireland is expected to fall substantially in 2019 due to increased revenues. This might be an overestimation as previous years' fast estimates were eventually revised upwards by 2 percentage points because of more precise revenue numbers.

<b>VAT GAP change since 2014</b>					<b>+3.4 pp</b>	

### Highlights

- VAT compliance in Greece showed a significant improvement in 2018 (a decrease of the VAT Gap by 3.1 percentage points down to 30.1 percent).
- Fast estimate suggests that next year the VAT Gap will increase above 31%.

Table 3.9a. Spain: VAT Revenue, VTTL, Composition of VTTL, and VAT Gap, 2014-2018 (EUR million)

<b>VAT GAP change since 2014</b>					<b>-4.1 pp</b>	

### Highlights

- Between 2015 and 2018, the VAT Gap has remained relatively stable at a level of 6 percent of the VTTL.
- The results were revised due to the update of Eurostat's revenue figures.

**Table 3.9b. Spain: Alternative Estimates**

<b>Spain</b>	<b>2014</b>	<b>2015</b>	<b>2016</b>	<b>2017</b>	<b>2018</b>
<i>VAT Gap based on alternative data</i>	2,946	2,177	2,680	2,925	1,737
<i>VAT Gap based on alternative data, as a percent of VTTL</i>	4.3%	3.1%	3.7%	3.8%	2.2%

*Note: Adjusting revenues for the continuing reduction in the stock of claims and adjusting the VTTL for the difference between national accounting and tax conventions in the construction sector based on the data received from Spanish Tax Authorities led to a downward revision of the VAT Gap for the entire period 2014-2018.*

<b>VAT GAP change since 2014</b>					<b>-5.4 pp</b>	

### Highlights

- The VAT Gap in Croatia fell in 2018 by 2 percentage points down to 3.5 percent of the VTTL.
- Since 2015, the Gap has followed a downward trend and is expected to do so in 2019 as well.

### Highlights

- Over the analysed period, the VAT Gap in Italy has followed a downward sloping trend, reaching 24.5 percent of the VTTL in 2018.
- Thanks to information provided by the Tax Authorities, the time break in the intermediate consumption of public administration in Eurostat's SUT was corrected.

**Table 3.12b. Italy: Alternative Estimates**

<b>Italy</b>	<b>2014</b>	<b>2015</b>	<b>2016</b>	<b>2017</b>	<b>2018</b>
VAT Gap based on alternative data	38,256	38,880	38,294	38,194	34,743
VAT Gap based on alternative data, as a percent of VTTL	28.1%	28.1%	27.5%	27.0%	24.0%

*Note: The estimates above are based on adjusted revenues for the changes in outstanding stocks of net reimbursement claims (to better approximate accrued revenues) and Italy's own estimates of illegal activities, namely illegal drugs and prostitution activities.*

Table 3.13. Cyprus: VAT Revenue, VTTL, Composition of VTTL, and VAT Gap, 2015-2018 (EUR million)

<b>VAT GAP change since 2015</b>					-6.0 pp	

### Highlights

- Thanks to information from the Tax Authorities, revenue figures were corrected to account for the expected backward revisions of Eurostat's figures.
- Due to expected revision of national accounts and an important component of the country-specific adjustments and a potentially large estimation error, fast estimates for Cyprus are not published.

<b>VAT GAP change since 2014</b>					<b>-2.8 pp</b>	

### Highlights

- Over the period 2015-2018, the VAT Gap in Lithuania remained stable, amounting to 25 percent of the VTTL, on average.
- Based on fast estimates, it is expected that the VAT Gap will fall significantly in 2019 – by about 4 percentage points.

Table 3.16. Luxembourg: VAT Revenue, VTTL, Composition of VTTL, and VAT Gap, 2014-2018 (EUR million)

	2014	2015	2016	2017	2018	2019*

<b>VAT GAP change since 2014</b>					<b>+1.5 pp</b>	

### Highlights

- In 2018, the VAT Gap was 5.1 percent of the VTTL, which was a 2.5 percentage point incline year-over-year.
  - Due to an important component of the country-specific adjustments related to e-commerce and financial intermediation services and a potentially large estimation error, fast estimates for Luxembourg are not published.

### Highlights

- The VAT Gap in Malta fell by approximately 2.5 percentage points in 2018 down to 15.1 percent of the VTTL.
- As a net exporter of electronic services, VTTL and revenue in Malta was affected by the withdrawal of the MOSS retention fee as of 2019.
- The VTTL in Malta was revised significantly upwards thanks to the availability of data from fiscal registers allowing for more accurate estimations of the effective rates and propexes for financial and gambling services.

<b>VAT GAP change since 2014</b>					<b>-4.8 pp</b>	

### Highlights

- In 2018, the VAT Gap fell by 0.6 percentage points down to nearly 4 percent of the VTTL.
- Due to a substantial change in the VAT rates in 2019 and a potentially large estimation error, fast estimates for the Netherlands are not published.

### Highlights

- Over the period 2014-2018, the VAT Gap in Austria remained nearly constant, amounting to ca. 8-9 percent of the VTTL, on average.
- In 2019, the VAT Gap is expected to decrease by about 1.5 percentage points.

### Highlights

- In 2018, Poland recorded the third most significant decline of the VAT Gap in the EU of 4.3 percentage points down to 9.9 percent.
- The trend of significant decreases in the VAT Gap started in 2015 is expected to end in 2018 as the rate in 2019 will remain nearly identical.

### Highlights

- The VAT Gap in Portugal was just below the EU total (9.6 percent of the VTTL).
- It followed a downward trend over the analysed period. Between 2014 and 2018, the Gap fell by approximately one percentage point yearly, on average.

### Highlights

- In 2018, the VAT Gap remained nearly unchanged.
- Overall, between 2014 and 2018, the Gap fell by roughly 7 percentage points.
- The effective rates for certain categories (such as agricultural products, restaurants, and hotels) were modified based on legislation in order to improve consistency with other countries.

### Highlights

- The VAT Gap in Slovenia followed a downward trend over the analysed period. Between 2014 and 2018, the Gap fell by six percentage points, in total.
- This trend is expected to continue into 2019 with a decrease of another 2 percentage points.

### Highlights

- Sweden recorded the lowest VAT Gap in the EU in 2018 of about 0.7 percent of the VTTL.
- Fast estimates are not reported for Sweden as they suggest a slightly negative VAT Gap.

### Highlights

- The VAT Gap in the United Kingdom remained relatively stable over the 2014-2018 period.
- Effective rates were revised based on the new treatment of illegal goods smuggling and the rate of exemption for education services.

## 4. Policy Gap Measures for 2018

In this chapter, we present an update of the series of estimates of the Policy Gap and its components for the EU-28.

As discussed in the previous Reports, the Policy Gap captures the effects of applying multiple rates and exemptions on the theoretical revenue that could be levied in a given VAT system. In other words, the Policy Gap is an indicator of the additional VAT revenue that could theoretically (i.e. under the assumption of perfect tax compliance) be generated if a uniform VAT rate is applied to the final domestic use of all goods and services. Due to the idealistic assumption of perfect tax compliance and a very broad base that captures entire final consumption and households' GFCF, the practical interpretation of the Policy Gap draws criticism. Nonetheless, the assumption of perfect VAT collectability is indispensable, as interdependencies between tax compliance and rate structure are not straightforward.

In order to learn how different components contribute to revenue losses, we compose the Policy Gap into different components of revenue loss, as we show in Annex A.e. Such elements are, for instance, the Rate Gap and the Exemption Gap, which capture the loss in VAT liability due to the application of reduced rates and the loss in liability due to the implementation of exemptions, respectively.

Moreover, following Barbone et al. (2013), the Policy Gap and its components could be further adjusted to address the issue of the extent to which the loss of theoretical revenue depends on the decisions of policymakers. Measures that exclude liability from the final consumption of "imputed rents" (the notional value of home occupancy by homeowners), the provision of public goods and services, and financial services. For these specific groups of services, charging VAT is impractical or currently goes beyond the control of national authorities.

The estimates of the Policy Gap, Rate Gap, Exemption Gap, Actionable Policy Gap, and Actionable Exemption Gap for the EU-28 MS for 2018 are presented in Table 4.1.

For the EU overall, the average Policy Gap level was 44.24 percent. This means that the VAT that could currently be levied in the case of full compliance generates 44.24 percent of what could have been generated if all the exemptions and reduced rates were abolished and all final use according to national accounts' definition was taxed. Of this 44.24 percent, in 2018, 10.07 percentage points were due to the application of various reduced and super-reduced rates (the Rate Gap) and 34.17 were due to the application of exemptions without the right to deduct.

According to the Rate Gap estimates, reduced rates are least applied in Denmark (0.77 percent), Latvia (2.37 percent), and Estonia (2.68 percent). On the other side of spectrum are Cyprus (25.97 percent) and Italy (15.86 percent). The MS with the highest values of the Exemption Gap are Spain (43.59 percent), due to the application of other than VAT indirect taxes in the Canary Islands, Ceuta, and Melilla, and the United Kingdom (43.18 percent). The lowest value of the Exemption Gap was observed in Malta (15.79 percent).

The largest part of the Exemption Gap is composed of exemptions on services that cannot be taxed in principle, i.e. imputed rents and the provision of public goods (26.06 percent). The remaining level of the Exemption Gap is financial services (2.33 percent) and the “Actionable” Exemption Gap, which is 5.77 percent, on average.

The Actionable Policy Gap – a combination of the Rate Gap and the Actionable Exemption Gap – is 15.85 percent on average. This figure shows the combined reduction of Ideal Revenue due to reduced rates (10.07 percent) and exemptions (5.77 percent) which could possibly be removed.

In three cases, i.e. the financial services Gaps in Cyprus, Ireland and Malta and the Actionable Exemption Gap in Malta, negative gaps were observed. Although theoretically possible, this likely results from a measurement error<sup>7</sup>.

---

<sup>7</sup> The Exemption Gap could become negative in periods when input VAT exceeds potential output VAT, like periods of increased investment or when losses are incurred. The measurement error may result from difficulties in decomposing the components of the base, such as sectoral GFCF and net adjustments, and inaccuracies in the underlying data and parameters.

## 5. Econometric Analysis of VAT Gap Determinants

### a. Introduction

The examination of tax non-compliance determinants is not new to the economic literature. Most of the literature dealing with such factors focuses on personal income taxes, voluntary tax compliance, and deterrence effects. This focus is clearly related to data availability. The empirical studies are based mostly on micro-data gathered in surveys and audit statistics. Thus, they concentrate on the impact of individuals' characteristics (see e.g. Feinstein [1991]). Similarly, studies scrutinising the determinants of compliance in corporate and consumption taxation usually look at micro-level revenue figures from fiscal registers or audit data (see e.g. Casey and Castro [2015]). The studies based on fiscal registers and audit and survey data face an important limitation, i.e. the inability to observe the variability of determinants across tax systems and economies. A rather limited number of studies looking at such cross-country variations focus on the variation of dynamics in tax revenue (see e.g. Aizenman and Jinjarak, [2018]) or have a qualitative nature (see e.g. Keen and Smith [2007]).

The European Commission's VAT Gap Study made available a large set of standardised data on tax compliance from a group of countries with varying economic and institutional characteristics. The series are available across a time period long enough to cover economic upturns and downturns. As a result, the Study provides an opportunity to conduct econometric analyses looking at the determinants of tax non-compliance from a new perspective. The panel data derived from the VAT Gap Study have already been used by a number of researchers – such as Barbone et al. (2013), Zídková (2017), Lešnik et al. (2018), Poniatowski et al. (2018 and 2019), Szczypińska (2019), and Carfora et al. (2020).

The econometric analysis outlined in this Study extends the above-mentioned studies several-fold. Concerning the data preparation procedure, we eliminate potential bias in the data by correcting the VAT Gap series for each country for revisions in subsequent vintages of the Study. Moreover, we account for measurement errors, i.e. changes in the VAT Gap not related to change in compliance but rather to specific one-off factors. To deal with the scarcity of observations of exogenous variables, we perform a dummy variable adjustment. Although this operation rises the number of explanatory variables, overall it increases the degrees of freedom due to higher number of observations included in the estimation. In regard to the specification of the models, we extend the list of covariates relating to tax policy characteristics, macroeconomic variables, variables describing the structure of the economy, and proxies of tax fraud.

### b. Data and Variables

Our endogenous variable is the VAT Gap of country  $i$  in year  $t$  taken from each of the European Commission's VAT Gap Studies (i.e. the 2013, 2014, 2015, 2016, 2017, 2018, and 2019 Studies). To ensure the comparability of vintages across time, the data was transformed using the methodology described in the following section.

The wide set of covariates included in the analysis originates from the 2019 Study but includes around 16 new variables<sup>8</sup>. The covariates could be grouped as those describing tax policies, indicators of the macroeconomic situation, variables describing the exogenous factors to the tax administration economic characteristics of a country, and proxies of VAT fraud.

The inclusion of **tax policy characteristics** is expected to show how the various efforts of tax administrations relate to the VAT Gap in each country. It could be expected that the greater the efforts of the administration are, the higher the level of tax compliance, both voluntary and involuntary. Expenditure on tax administration in relation to GDP alone might not be enough to capture how effectively the funds are used – the “IT expenditure” variable is expected to pick up the effect of innovative processes introduced into administrative processes. Similarly, the “Administrative effectiveness” variable, meaning the independence of the tax administration from political pressures as well as the quality of policy formulation and implementation, should account for general proficiency in collecting taxes and the credibility of government.

The set of **macroeconomic variables** aims to explain the cyclical conditions that affect taxpayer behaviour. For example, the “Unemployment” variable should be able to capture situations when taxpayers face stronger incentives to evade tax liabilities due to the increased number of bankruptcies and liquidity constraints. Similarly, “GDP per capita” is expected to capture periods of economic stress as well as decreasing with wealth incentives not to comply. We also expect that the level of government debt could complement the list of core determinants by accounting for the economic constraints and prudence of public finance.

We suspect that certain economic characteristics which show large variation across countries and rather low variation in time are also related to VAT compliance. Thus, we include variables describing the sectoral and company **structure of the economy**. In particular, we distinguish the retail sector, which could be the key sector, along with other labour-intensive sectors, as well as real estate, construction, industry, telecommunications, and art. The model also takes into consideration the structure of companies by size of employment and the relative size of the shadow economy. One of the newly introduced variables is the value of credit transfer payments involving non-MFIs – this variable should help to explain how advanced the financial system is in terms of cashless transactions, which are more secure and easier to control by the tax administration.

Since the variability of **tax fraud**, a significant component of the VAT Gap, may be related to very specific factors not included in the covariates list, we proxy the scale of fraud using

---

<sup>8</sup> See Table 5.1, EC (2019).

three alternative approaches<sup>9</sup>. As one of the possible indicators of fraud, we look at international trade, as sudden changes – mostly in intra-Community purchase figures – may indicate an increasing scale of Missing Trader Intra-Community (MTIC) fraud. We also create a more refined indicator of trade at risk. This indicator was constructed by applying an algorithm which examined the differences over time in the reported values of traded goods known for being targeted by fraud (we used a list of goods that were placed under a reverse charge procedure). The relative differences between the values of trade reported by both sides were first smoothed using a moving average to limit the influence of short-term fluctuations. In the next step, this time series were treated with the k-means algorithm in order to identify possible “odd” values. In the last step, a set of filters was applied to these values in order to make sure that the discrepancies were significant and not an isolated event. The goal of this process was to identify periods where these differences were non-systematic, which in turn may indicate the emergence of fraud. In the final step, the values of the discrepancies were aggregated for each country and related to the total value of trade for goods under scrutiny. In addition, we look at the frequency of use of specific customs procedures (CPCs 42 and 63) which could be regarded as risky<sup>10</sup>. The full list of variables is included in Table 5.1 below.

Table 5.1. Variables

Variable	Source	No. of Obs.	Remarks	Expected Relationship
<b>Endogenous variable</b>				
VAT Gap	VAT Gap reports, EC	Yearly data of 26-28 MS observed between 2000 and 2017	The data will be gathered from published VAT Gap reports utilising the most recent vintage available	-

### c. Methods and Approach

The VAT Gap estimates presented in each release of the Study have been updated recursively whenever new information became available. Specifically, there are three different sources of VAT Gap revisions<sup>11</sup>. However, the revisions have one important property. As shown in Figure 5.1, they have a minor impact on the dynamics of the Gap for periods when full information is available.

**Figure 5.1. Comparison of Results (VAT Gap as % of the VTTL in EU-28)**

Source: own elaboration based on EC (2013, 2014, 2015, 2016, 2017, 2018, and 2019).

As the updates do not impact year-over-year changes in the VAT Gap, but only in magnitudes, we derived past estimates of the VAT Gap for each and every MS using a backcasting procedure. The backcasting procedure relies on the magnitude of values for a period of 5 years covered by the most recent estimates. At the same time, the dynamics, i.e. year-over-year changes in percentage points, for the years not covered by the full estimates are based on previous Studies (the most recent Study available including specific years). For instance, the estimates for 2000-2013 included in 2020 Study rely on the seven

<sup>11</sup> See Annex A.a. for more details.

studies published between 2013 and 2019 but were adjusted to the magnitude of full estimates for 2014-2019.

Such a procedure has not been used in any of the previous studies. In our view, despite using fixed effects specifications, such a procedure eliminates potential problems stemming from the revisions, which might be correlated both in time and across entities.

For aggregate EU-wide figures, this backcasting is depicted by Figure 5.2, whereas the time series for each country are depicted by Figure 5.3. Figure 5.4 shows estimates for each country published in consecutive vintages of the Study.

**Figure 5.2. Backcasting of EU-wide Estimates Presented in Figure 5.1 (VAT Gap as % of the VTTL)**

Source: own elaboration based on EC (2013, 2014, 2015, 2016, 2017, 2018, and 2019)

As shown in Table 5.1, the explanatory variables are often available for only a subset of observations. The nature of missing data varies across variables. Some data sources cover only specific MS (e.g. OECD), other sources are available for the most recent years only (Surveillance database) or were discontinued (e.g. Verification actions). However, there is one important similarity – data is not missing at random in most instances.

The problem of the unavailability of observations markedly decreases the number of degrees of freedom in the models with numerous exogenous side variables introduced. This creates a trade-off between two econometric problems – omitted variables and insufficient degrees of freedom.

To reduce the scale of the problem, we impute the values of the missing variables. We use a simple and intuitive method that partially controls the bias created by the non-random character of the missing data (Allison, 2001). The procedure for missing predictors in regression analysis that we use is called dummy variable adjustment or the missing indicator method. In this approach, if  $X$  is an incompletely observed predictor in a regression model, then a binary response indicator for  $X$  is created ( $RX = 1$ , if the value in  $X$  is missing;  $RX = 0$ , if the corresponding value in  $X$  is present). Then, it is included in the regression model together with missing values in  $X$ , which are filled in with any constant value  $c$ .

The method that we use increases the number of observations substantially but also creates a bias (Kleinke et al., 2011). Allison (2001) concluded that the method generally yields biased coefficient estimates and should only be applied in certain situations, for example when the unobserved value simply could not exist. The imputation could not use more refined techniques like the procedure proposed by Little and Rubin (1987) since the multivariate data are neither missing completely at random nor the conditionality of missing data could be controlled.

In accordance with the *Data and variables* section<sup>12</sup>, the basic regression takes the form<sup>12</sup>:

$$VG_{it} = \alpha_1 TAV_{it} + \alpha_2 MV_{it} + \alpha_3 ESV_{it} + \alpha_4 FP_{it} + a_t + a_i + u_{it}$$

The endogenous variable is the VAT Gap for country  $i$  in year  $t$ ,  $VG_{it}$ , which might be explained by the variables related directly to the actions taken by tax administrations ( $TAV_{it}$ ), control variables describing the current macroeconomic situation ( $MV_{it}$ ), control variables describing the characteristics of specific MS (economic structure variables -  $ESV_{it}$ ), and fraud proxies ( $FP_{it}$ ). These variables are characterised by a small variation over time and a relatively large variation across countries. Apart from these variables, we include fixed effects by country ( $a_i$ ), such that the expression above is a fixed effects model, and year

<sup>12</sup> We also tested the alternative structure of the equation, i.e. the logarithmic form. However, the measures of the model's fit pointed to selecting the non-log form of the model.

time effects ( $a_t$ ) (within estimator). Finally,  $u_{it}$  is the error term with the classical statistical properties.

A fixed effects model seems particularly appropriate, as one could argue some explanatory factors like the efforts of the tax administration or institutional variables might be correlated with many other factors that are not included in the regressions. The drawback is that the estimates of the fixed effects are uninterpretable, meaning that part of the variation cannot be attributed to specific factors. We are also unable to estimate the impact of the variables that show little within-country variation, as for example, level of VAT tax rates or firm size.

As some of the listed variables are significantly correlated with others, we bear in mind the potential collinearity and endogeneity problem, which is tackled by the careful selection of variables for each specification.

#### d. Results

Due to the multiplicity of covariates and the enormous number of potential combinations of model specifications, we have proceeded parsimoniously. The approach consisted of three stages. In the first stage, we have run Bayesian Model Averaging to learn which variables are not significant in the majority of specifications' variations. In the second stage, we created a correlation matrix of the remaining variables to learn which are collinear and cannot be presented in common specifications. Finally, we eliminated specifications on the basis of tests presented in Annex A.

The narrow dataset obtained after the first stage consisted of 27 explanatory variables. A summary of the statistics of these variables is shown in Table 5.2.

**Table 5.2. Descriptive Statistics**

	<i>n</i>	<i>Mean</i>	<i>Minimum</i>	<i>Maximum</i>	<i>Standard Deviation</i>

Intra-EU import at risk (share in GDP)	485	0.01	0.00	0.07	0.01

Source: own elaboration.

The results of our regressions are shown in Table 5.3. The simplest model, the baseline specification, which is later used for predictions and robustness checks, is described in column (1). As can be seen in the Table, GDP growth, general government surplus, IT expenditure, trade at risk, and the shares of the agriculture, communication services, and financial sectors are all statistically significant at the 5 percent level of significance. According to the estimation results of the baseline specification, in order to decrease the VAT Gap by one percentage point, GDP needs to increase by 3.6 percentage points more, the general government balance needs to improve by 3.4 percentage points, the share of IT expenditure in the overall expenditure of tax administrations needs to increase by roughly 5.4 percentage points, or the share of risky imports of goods in GDP needs to increase by one percentage point<sup>13</sup>.

The alternative specifications (columns (2) to (9)) show that a number of variables that were suspected to be related to changes in the VAT Gap appeared to be statistically insignificant at the  $p=0.05$  level. This concerns some of the tax administration variables, i.e. the frequency of verification actions, the Fiscal Rules Index, and the frequency of electronic payments. The alternative fraud proxies, namely discrepancies in Intrastat registers and the frequency of using CPCs 42 and 64 appeared to be more weakly inter-related with the Gap

<sup>13</sup> The impact of changes in the value of exogenous variables is derived under *ceteris paribus* assumption, by dividing one over the respective coefficient value.

as compared to the cross-border trade in risky goods. The alternative specifications also show that the share of small and medium-sized companies if measured by their share in overall employment could have a positive impact on the VAT Gap. However, due to the inter-relation between the sectoral structure of the economy and firm size, we decided to remove the firm size variable from the baseline equation. The equation with sectoral share variables appeared to translate larger proportion of variation than the equation with firm-size variables (column (5) and (6)).

As a robustness check on the fixed effects specification, we show how the estimates of the model vary across time and countries. Table 5.4 shows the comparison of the baseline estimation with the estimation performed separately across different time periods: 2000-2011 (which were reported in the 2013 Study) and 2006-2017 (which were reported across subsequent studies). Columns 4 and 5 report the estimates for low and high VAT Gap countries. The last column shows the model estimated with the full interaction of the time period dummy and explanatory variables. In other words, such a specification allowed to differentiate the value of parameters between low and high VAT Gap Member States.

Table 5.4 shows that the baseline model and the model estimated on the 2000-2011 period show very similar results in the values of the estimated effects. In the model estimated on the 2006-2017 time period only (reducing the observations by half), the estimates remain similarly robust. In the equations estimated on different subgroups of countries, general government balances, IT expenditure, communication, and financial sectors, as well as import of risky products remain robust as well. The largest heterogeneity is observed for the share of agricultural sector, which changes sign in the models estimated on the 2006-2017 period and low VAT Gap Member States. Moreover, GDP growth coefficient appeared not to be significant for low VAT Gap countries at the  $p=0.05$  level.

Aside from several robustness checks that were performed in order to assess the stability of the coefficients, we also look at the linear predictions for each MS (see Figure 5.5). They show that the model is accurate in predicting trends in VAT Gap changes.

As Figure 5.6 shows, the model is able to attribute the majority of shifts in the overall EU VAT Gap to specific factors despite the time-effects used in the model (see Figure 5.6). The results yield an important conclusion – much of the variation in the VAT Gap, especially in periods of economic stress, comes from cyclical factors. The decrease in the VAT Gap in recent years is however only partially related to positive economic tailwinds. Most of the changes are attributed to year effects, which are likely related to efforts of tax administrations not captured by the model.

## 6. The Potential Impact of the Coronavirus Recession on the Evolution of the VAT Gap

In this chapter, we examine the potential impact of the coronavirus recession on future VAT collections. The objective is to illustrate that both a decrease in the base as well as an increase in VAT non-compliance will negatively affect VAT revenue over the 2020-21 period.

To conduct our forecasts, we operationalise the numerical evidence from the econometric analysis presented in the preceding chapter. We use the coefficients of the interrelations between the VAT Gap and the macroeconomic indicators in the baseline model specification and the Spring Commission's macroeconomic forecasts as inputs. The predictions are based on the number of assumptions. Not only do we assume that the macroeconomic forecasts will be accurate, but we also assume that the control variables unrelated to the economic situation will not change. For this reason, prediction intervals are relatively large. The results for the EU are reported in the previous section, whereas the indicative results for each EU MS are shown in Annex C.

The ongoing COVID-19 recession that will be covered by future VAT Gap Studies is rapidly changing the conditions for collecting VAT, which have remained favourable in recent years. Due to the pandemic, in May 2020, the European Commission significantly revised its forecast of the main economic indicators<sup>16</sup>. It was estimated that the EU's GDP as a whole could contract by 7.4 percent in 2020 and grow by 6.1 percent in 2021 if the following scenario materialises:

- a) the number of infections in the EU will remain under control even after the loosening of containment measures,
- b) most of the lockdown measures will be gradually lifted and economic activity will not be affected greatly by the measures that will be kept in place, and
- c) economic policies put in place by MS governments and the EU will prove to be effective in preventing high unemployment and mass bankruptcies.

As shown in Figure 6.1, the estimates point to a rapid decline in GDP growth and a deterioration of general government balances in 2020. As a result of the recession, the VAT Gap in 2020 is forecasted to increase by 4.1 percentage points up to 13.7 percent (Figure 6.2 and 6.3). The hike in 2020 could be more pronounced than the gradual decrease of the Gap over the three preceding years. This means that the VAT Gap, as a percent of the VTTL, will be higher than in 2016 (Figure 6.3). In nominal terms, the VAT Gap is expected to reach over EUR 164 billion in 2020. A relatively smaller increase of the nominal VAT Gap

---

<sup>16</sup> At the moment of publication of this Study, more up to date (interim) Summer Forecasts became available. However, as they did not include projections of government balances necessary for our projections, they were not included herein.

is related to the sudden decline in the base over the forecasting period. Similarly, to aggregate results, the VAT Gap in most MS will fall rapidly in 2020 and will not fully recover by 2021. The least significant decline in compliance is expected in the EU MS predicted to be least affected by the economic crisis, such as Slovakia and Poland (see Annex B, Table B7 and Annex C)<sup>17</sup>.

In 2021, the EU economies are expected to recover but only partially. It is expected that despite the stimulus measures introduced, the level of GDP in all EU MS will remain below 2019 nominal values and general government balances will be substantially worse than in 2019. If this scenario materialises, the VAT Gap in the EU would fall in relative terms compared to 2020 but would be unlikely to reach the 9.6 percent estimated for 2019. The scenario for 2021 still poses a number of uncertainties. For this reason, the model forecasts were not visualised herein.

---

<sup>17</sup> The forecasts are presented only for Member States, for which fast estimates for 2019 were available, namely EU28 excluding Cyprus, Luxembourg, Malta and the Netherlands.

<sup>18</sup> The prediction intervals were estimated for 95% on the basis of the standard errors of the actual VAT Gap estimates for 2016 and 2017 and the estimates of the model using a 2001-2015 series.

## Annex A. Methodological Considerations

This section of the Annex is based to a large extent on the methodological considerations already presented in earlier VAT Gap Reports. More detailed considerations regarding the approaches to estimate the VAT Gap are presented in the seminal VAT Gap Report (Barbone et al., 2013).

### a. Source of Revisions of VAT Gap Estimates

Every year, the estimates of the VAT Gap are updated and revised backwards. There are three different sources of such revisions:

- 1) Updates in the underlying national accounts data published by Eurostat: updates in VAT revenues, new supply and use tables, and revised industry-specific growth rates, among others.
- 2) Updates in the estimated GFCF liability, based on the new information from the own resource submissions (ORS) on taxable shares of GFCF by five sectors: households, government, NPISH, and exempt financial and non-financial enterprises.
- 3) Revision of the parameters of the VTTL model: effective rates, pro-rata coefficients, and net adjustments, either due to new information from ORS or due to correcting errors in the previous computation.

In nominal terms, the most significant revisions in 2018 concerned Malta. The revision of the VTTL in Malta resulted from the availability of data from fiscal registers allowing for a more accurate estimation of the effective rates and propexes for four sectors crucial for the Maltese economy and its output, namely *Financial services, except insurance and pension funding* (NACE and CPA 64), *Insurance, reinsurance and pension funding services, except compulsory social security* (NACE and CPA 65), *Services auxiliary to financial services and insurance services* (NACE and CPA 66), and *Gambling and betting services* (NACE and CPA 92). Another noteworthy revision concerned Ireland and Germany. The estimates for these two countries were revised backwards due to an improved methodology for imputing missing and confidential values in Eurostat's SUT.

## b. Decomposition of VAT Revenue

As VAT Revenue (VR) is the difference between the VTTL and the VAT Gap ( $VR = VTTL - VAT\ Gap$ ), and the VTTL is a product of the effective rate and the base ( $VTTL = effective\ rate \times base$ ), VAT revenue could be decomposed using the following formula:

$$VR = VTTL \times VAT\ compliance = effective\ rate \times base \times \left(1 - \frac{VAT\ Gap}{VTTL}\right)$$

Thus, the year-over-year relative change in revenue is denoted as:

$$\frac{\Delta VR}{VR} = \frac{\Delta(effective\ rate)}{effective\ rate} \times \frac{\Delta base}{base} \times \frac{\Delta\left(1 - \frac{VAT\ Gap}{VTTL}\right)}{\left(1 - \frac{VAT\ Gap}{VTTL}\right)}$$

where  $\frac{\Delta(effective\ rate)}{effective\ rate}$  denotes change in effective rate,  $\frac{\Delta base}{base}$  denotes change in base, and  $\frac{\Delta\left(1 - \frac{VAT\ Gap}{VTTL}\right)}{\left(1 - \frac{VAT\ Gap}{VTTL}\right)}$  denotes change in VAT compliance.

## c. Data Sources and Estimation Method

The method used to estimate the VAT Gap in this report uses a “top-down” approach. Top-down approaches rely on national accounts, which cover the full tax base and are an exhaustive description of all productive activities. On the contrary, “bottom-up” approaches use data gathered by tax administrations including audits, surveys, and enquiry programmes. This enables us to estimate non-compliance in VAT for specific taxpayer groups as well as types of non-compliance.

Within top-down approaches, VAT liability can be calculated using a “consumption-side” approach focused on the last link in the VAT chain (including intermediate consumption for exempt services) or a “production-side” approach that considers VAT due by each sector of economic activity<sup>19</sup>. If the choice of underlying observations is random or if it is possible to estimate selection bias, a “bottom-up” approach might be used to derive the economy-wide tax gap figure.

Aside from the different methodologies used, estimates of tax gaps could also be differentiated by the treatment of the tax collected by audit activities and assessed but finally not collected. The estimates presented herein show a “net” gap, meaning that they account for all revenue, including late payments and VAT collected in audit procedures. Estimates of a “gross gap” containing only the liabilities paid on time would be larger.

In the “top-down consumption-side” method that is utilised in this Report, the VTTL is estimated as the sum of the liability from six main components: household, government,

<sup>19</sup> For more details see IMF (2017).

and NPISH final consumption; intermediate consumption; GFCF; and other, largely country-specific, adjustments.

In the “top-down” approach, the VTTL is estimated using the following formula:

$$\begin{aligned}
 VTTL = & \sum_{i=1}^N (rate_i \times Value_i) \\
 & + \sum_{i=1}^N (rate_i \times propex_i \times IC Value_i) \\
 & + \sum_{i=1}^N (rate_i \times propex_i \times GFCF Value_i) + net\ adjustments
 \end{aligned}$$

Where:

*Rate* is the effective rate,

*Value* is the final consumption value,

*IC Value* is the value of intermediate consumption,

*Propex* is the percentage of output in a given sector that is exempt from VAT,

*GFCF Value* is the value of gross fixed capital formation, and

index *i* denotes sectors of the economy.

To summarise, the VTTL is a product of the VAT rates and the propexes multiplied by the theoretical values of consumption and investment (plus country-specific net adjustments).

For the purpose of VAT Gap estimation, roughly 10,000 parameters are estimated for each year, including the effective rates for each 2-digit CPA (i.e. *rate<sub>i</sub>* in the VTTL formula presented above) group of products and services and the percentage of output in a given sector that is exempt from VAT for each type of consumption (i.e. *propex<sub>i</sub>* in the VTTL formula presented above). For instance, for *Education services* (CPA no. 85) in Croatia, like for any other country and group of products and services, we estimated effective rates in household, government, and NPISH final consumption, as well as the percentage of output that is exempt from VAT. The main source of information is national accounts data and ORS, i.e. VAT statements provided by MS to the European Commission. In a number of specific cases where ORS information was insufficient, additional data provided by MS were used. As these data are not official Eurostat publications, we decline responsibility for inaccuracies related to their quality.

A complete description of data and sources is shown in Table A1.

Table A1. Data Sources

	DESCRIPTION	PURPOSE	SOURCE	COMMENT
1	Household expenditure by CPA/COICOP category.	Estimation of effective rates for household final consumption for each 2-digit CPA category.	ORS / HBS <sup>20</sup>	...
2	The intermediate consumption of industries for which VAT on inputs cannot be deducted, pro-rata coefficients, alternatively share of exempt output.	Estimation of propexes.	ORS / assumptions common for all EU MS	...
3	Investment (gross fixed capital formation) of exempt sectors.	Estimation of VAT liability from investment.	ORS / Eurostat	Values forecasted two years ahead of available time series.
4	Government expenditure by CPA/COICOP category.	Estimation of effective rates for government final consumption for each 2-digit CPA category of products and services.	ORS	Only individual government consumption and social transfers in kind specifically are a part of the tax base. However, the effective rate is estimated using a broad definition of the base that includes entire government consumption.
5	NPISH expenditure by CPA/COICOP category.	Estimation of effective rates for NPISH final consumption for each 2-digit CPA category of products and services.	ORS	...
6	VTTL adjustment due to small business exemption, business expenditure on cars and fuel, and other country-specific adjustments.	Estimation of net adjustments.	ORS	In general, adjustments forecasted two years ahead of available time series.
7	Final household consumption, government final consumption, NPISH final consumption, and intermediate consumption.	Estimation of VTTL.	Eurostat	As national accounts figures do not always correspond to the tax base, two corrections to the base are applied: (1) adjustments for the self-supply of food and agricultural products and (2) adjustments for the intermediate consumption of construction work due to the treatment of construction activities abroad.  If use tables are not available for a particular year or available use tables include confidential values, use tables are imputed using the RAS method <sup>21</sup> .
8	VAT revenue.	VAT revenue.	Eurostat	...

Source: own.

<sup>20</sup> Household Budget Survey, Eurostat.

<sup>21</sup> The RAS method is an iterative proportional fitting procedure used in a situation when only row and column sums of a desired input-output table are known.

#### d. Fast VAT Gap Estimates

The methodology used to estimate the VTTL for 2019 differs markedly from the one employed to estimate the VTTL for 2014-2018. The main simplifications and assumptions include:

- 1) Structure of household final consumption does not change with respect to 2017. In fact, due to the unavailability of up-to-date figures, it relies in most cases on a three-year lagged series.
- 2) Non-deductible GFCF liability changes in line with the year-over-year change in government GFCF published by AMECO<sup>22</sup>.
- 3) In the vast majority of cases where there are no significant changes in the statutory rates, net adjustments and intermediate consumption liability are rescaled from 2017 using growth rates for the entire tax base.

Due to the simplified methodology, uncertainty around the “fast estimates” is substantially larger than for the full estimates. For three MS, namely Cyprus, Luxembourg, and the Netherlands, the estimation error was exceptionally large due to the considerable role of country-specific adjustments or to significant changes in the policy structure; hence, we decided not to publish these estimates. The “fast estimates” for 2019 are to be found in the Individual Country Results pages (Tables 3.1 to 3.28) and Annex B.

The accuracy of the fast estimates depends on the stability of the structure of the liability components, which results, among others, from economic conditions and tax policies. Regarding the “fast estimates” for 2018 published in the 2019 Report, the direction of year-over-year change was 78 percent in line with the change in sign indicated by the full estimates in the this Report. The mean prediction error was 1.05 percentage points. This relatively small error margin validates our approach and encourages us to continue the publication of the “fast estimates”.

#### e. Derivation of the Policy Gap

This section of the Annex defines the concepts used in Chapter 5 for estimating foregone revenue due to policies introduced and discusses some of the methodological considerations.

We begin with the **Notional Ideal Revenue** that, by definition, should indicate an upper limit of VAT revenue (i.e. the revenue levied at a uniform rate in the environment of perfect tax compliance). As shown in Figure A1, ideal revenue is larger than the VTTL and subsequently larger than VAT collection. However, due to the existence of exemptions, it

---

<sup>22</sup> Source: [https://ec.europa.eu/info/business-economy-euro/indicators-statistics/economic-databases/macro-economic-database-ameco\\_en](https://ec.europa.eu/info/business-economy-euro/indicators-statistics/economic-databases/macro-economic-database-ameco_en)

does not capture the entire VTTL and tax collection. If no exemptions were applied, neither intermediate consumption nor the GFCF of the business sector would be the base for computing the VTTL.

The problem arises when deciding whether investment by the non-business sector should be part of the VAT base. According to the OECD (2014), Notional Ideal Revenue is defined as the standard rate of VAT times the aggregate net final consumption. Multiplying the standard rate and final consumption would yield, however, lower liability than in the case where a country applied no exemptions, no reduced rates, and was able to enforce all tax payments. In real life, the VTTL is comprised partially from VAT liability from investment made by households, government, and NPISH. In the case of the non-inclusion of this investment to the base, the VTTL would be partially extended beyond the ideal revenue despite “no exemptions” present in the system (see Figure A1 (c)).

Policymakers can see the upper limit of VAT revenue by considering all final use categories of the household, non-profit, and government sectors. Thus, in this Report, Notional Ideal Revenue is defined as the standard rate of VAT times the aggregate net final and net GFCF of the household, non-profit, and government sectors, as recorded in the national accounts (interdependence among the various concepts presented is shown in Figure A1)<sup>23</sup>.

The **Policy Gap** is defined as one minus the ratio of the “legal” tax liability (i.e. the chunk of the Notional Ideal Revenue that, in the counterfactual case of perfect tax compliance, is not collected due to the presence of exemptions and reduced rates). The Policy Gap is denoted by the following formula:

$$\text{Policy Gap} = (\text{Notional Ideal Revenue} - \text{VTTL}) / \text{Notional Ideal Revenue}$$

The Policy Gap could be further decomposed to account for the loss of revenue. Such components are the **Rate Gap** and the **Exemption Gap**, which capture the loss in VAT liability due to the application of reduced rates and the loss in liability due to the implementation of exemptions.

The Rate Gap is defined as the difference between the VTTL and what would be obtained in a counterfactual situation, in which the standard rate, instead of the reduced, parking, and zero rates, is applied to final consumption. Thus, the Rate Gap captures the loss in revenue that a particular country incurs by adopting multiple VAT rates instead of a single standard rate (Barbone et al., 2015).

The Exemption Gap is defined as the difference between the VTTL and what would be obtained in a counterfactual situation, in which the standard rate is applied to exempt

---

<sup>23</sup> National accounts for most countries report final consumption on a gross (i.e. VAT-inclusive) basis. Net consumption is estimated on the basis of the gross consumption recorded in the use tables, from which VAT revenues are subtracted.

products and services, and no restriction of the right to deduct applies<sup>24</sup>. Thus, the Exemption Gap captures the amount of revenue that might be lost because of exempted goods and services. Note that the Exemption Gap is composed of the loss in the VAT on the value added of exempt sectors, minus the VAT on their inputs, minus the VAT on GFCF inputs for these sectors. Thus, in principle, the Exemption Gap might be positive or negative (if the particular sector had negative value added, or if it had large GFCF expenditures relative to final consumption) (Barbone et al., 2015).

In algebraic terms, we have the following:

**Definitions:**

$T_i^{*,E} = \frac{VTTL_i^{*,E}}{C_i}$  – effective rate for group  $i$  of products in the case where the standard rate instead of the zero rate, parking rate, or reduced rate is applied (for final consumption and the GFCF of non-business activities).

$VTTL_i^{*,E}$  – liability from final consumption and GFCF of the non-business activities of group  $i$  of products, in the case where the standard rate instead of the zero rate, parking rate, or reduced rate is applied. Actual liability from intermediate consumption and the GFCF of business activities is assumed.

$T_i^{*,R} = \frac{VTTL_i^{*,R}}{C_i}$  – effective rate for group  $i$  of products in the event where exempt products within the group are taxed at the standard rate.

$VTTL_i^{*,R}$  – liability from the **final consumption** of group  $i$  when exempt products within the group are taxed at the standard rate. Actual liability from final consumption GFCF of non-business activities is assumed.

$\tau_s$  – statutory rate.

$i \in (1; 65)$  – sectors of the economy.

---

<sup>24</sup> The additive decomposition of the Policy Gap into the Exemption and Rate Gap presented in this Report differs from that in Keen (2013). Keen (2013) defines the Rate Gap as the loss from applying reduced and zero rates to the final consumption liability, measured as a percentage of the Notional Ideal Revenue. The Exemption Gap measures unrecovered VAT accumulated in the production process as a percentage, on the contrary, of final consumption liability. Due to these definitions, the Policy Gap can be split multiplicatively into gaps attributable to reduced rates and exemptions. Since the numerator of the “[1 - Rate Gap]” and denominator of the “[1 - Exemption Gap]” are equal, multiplication of these two components yields – VAT revenue as a percentage of Notional Ideal Revenue, which equals “[1 - Policy Gap]” (Barbone et al., 2015).

**Policy Gap:**

$$1 - P = \left( \frac{\sum_{i=1}^N T_i C_i}{\tau_s \sum_{i=1}^N C_i} \right) \left( \frac{\sum_{i=1}^N T_i^* C_i}{\sum_{i=1}^N T_i C_i} \right) = \left( \frac{\sum_{i=1}^N T_i^* C_i}{\tau_s \sum_{i=1}^N C_i} \right)$$

**Exemption Gap:**

$$1 - P_E = \left( \frac{\sum_{i=1}^N T_i C_i}{\tau_s \sum_{i=1}^N C_i} \right) \left( \frac{\sum_{i=1}^N T_i^{*,E} C_i}{\sum_{i=1}^N T_i C_i} \right) = \left( \frac{\sum_{i=1}^N T_i^{*,E} C_i}{\tau_s \sum_{i=1}^N C_i} \right)$$

**Rate Gap:**

$$1 - P_R = \left( \frac{\sum_{i=1}^N T_i C_i}{\tau_s \sum_{i=1}^N C_i} \right) \left( \frac{\sum_{i=1}^N T_i^{*,R} C_i}{\sum_{i=1}^N T_i C_i} \right) = \left( \frac{\sum_{i=1}^N T_i^{*,R} C_i}{\tau_s \sum_{i=1}^N C_i} \right)$$

By definition we have:

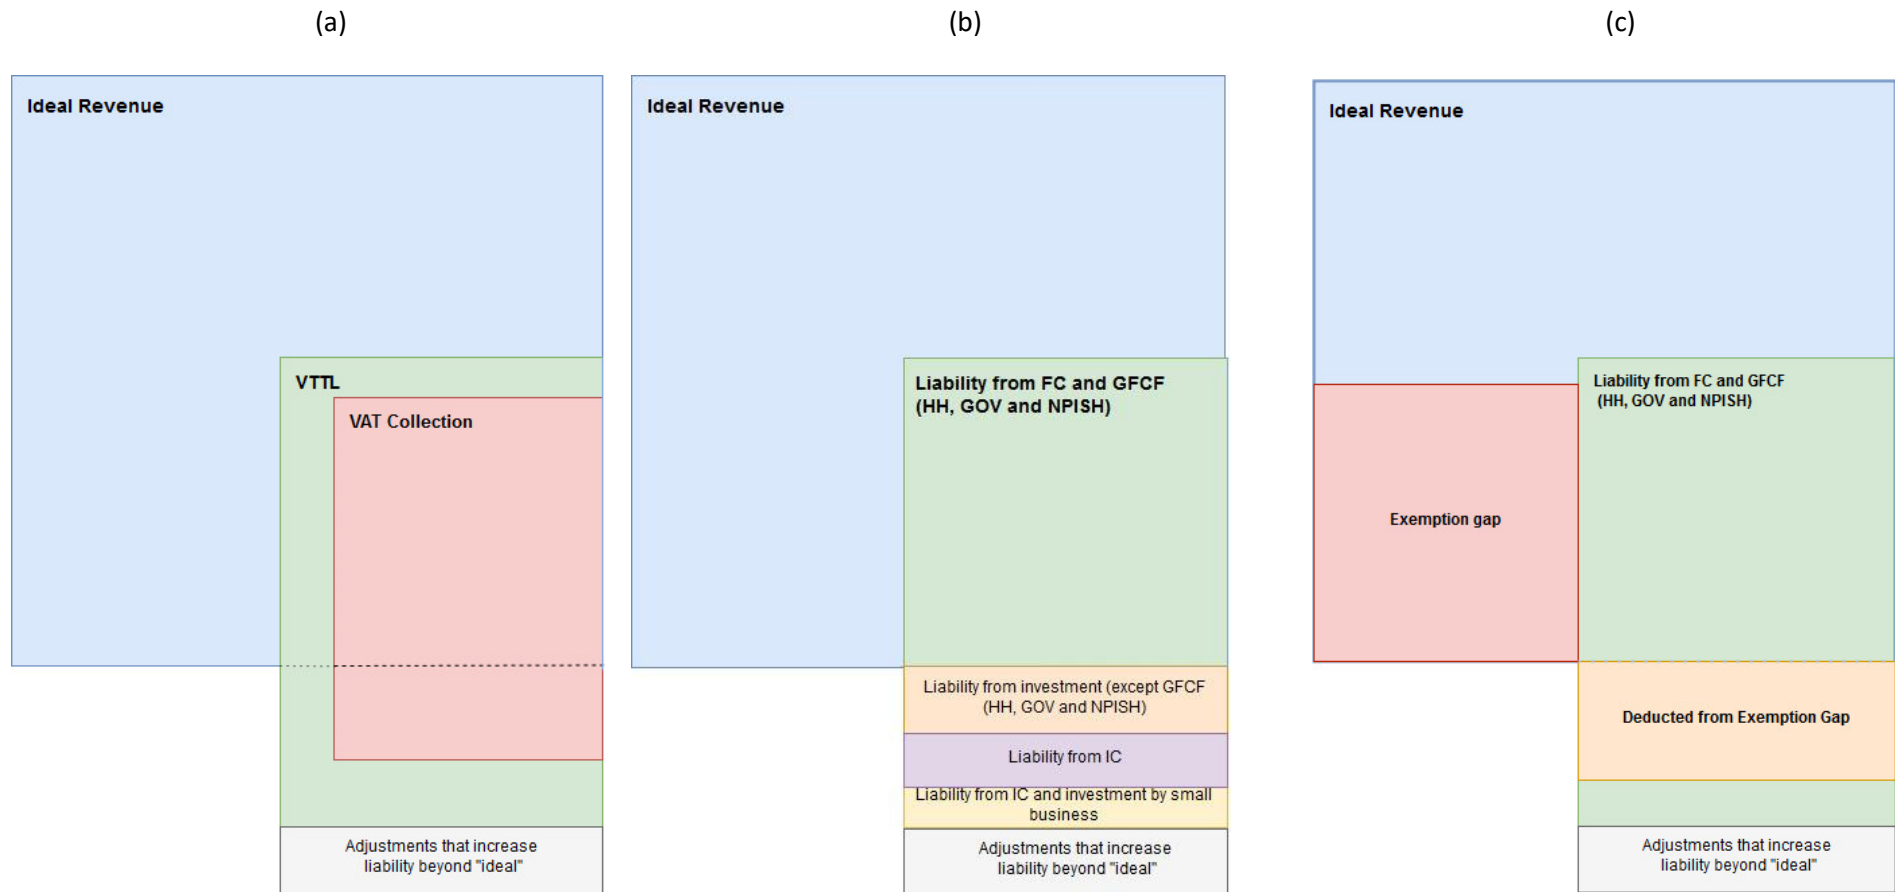

$$\begin{aligned} \tau_s \sum_{i=1}^N C_i &= \sum_{i=1}^N T_i^* C_i + \left( \tau_s \sum_{i=1}^N C_i - \sum_{i=1}^N T_i^* C_i \right) \\ &= \sum_{i=1}^N T_i^* C_i + \left( \tau_s \sum_{i=1}^N C_i - \sum_{i=1}^N T_i^{*,R} C_i \right) + \left( \tau_s \sum_{i=1}^N C_i - \sum_{i=1}^N T_i^{*,E} C_i \right) \end{aligned}$$

Thus:

$$P = 1 - \left( \frac{\sum_{i=1}^N T_i^* C_i}{\tau_s \sum_{i=1}^N C_i} \right) = \left( \frac{\tau_s \sum_{i=1}^N C_i - \sum_{i=1}^N T_i^* C_i}{\tau_s \sum_{i=1}^N C_i} \right) = \left( \frac{2\tau_s \sum_{i=1}^N C_i - \sum_{i=1}^N T_i^{*,E} C_i - \sum_{i=1}^N T_i^{*,R} C_i}{\tau_s \sum_{i=1}^N C_i} \right) = P_R + P_E$$

Using the above convention, one can decompose the Rate Gap and the Exemption Gap into components indicating the loss of the Notional Ideal Revenue due to the implementation of reduced rates and exemptions on specific goods and services. Such additive decomposition is carried out for the computation of, as defined by Barbone et al. (2015), the Actionable Exemption Gap, which excludes the services and notional values that are unlikely to be taxed even in an ideal world.

Figure A1. Components of Ideal Revenue, VTTL, and VAT Collection

#### **f. Tests of the Econometric Model**

Within the procedure for selecting exogenous variables aiming at minimising the problems of endogeneity, multicollinearity, and the omitted variables, we created a correlation matrix of pre-selected exogenous variables. As this test proved, there was no case of pairwise correlation of above 0.65 in the specifications presented in Table 5.4. To test whether the data matrix could result in unstable coefficient estimates, we used singular value decomposition method. In all of the data matrices underlying baseline and alternative equations, condition numbers were lower than 30, which is associated with well-behaved data matrices.

Several other statistical tests were performed. The appropriateness of including time and country fixed effects was verified through the Hausmann tests. As the tests indicated that in the random effects specification, errors are correlated with the regressors, the fixed effects specification was chosen.

Since the model contains time series, we verified that the model does not suffer from the issue of spurious regression. For this purpose, we performed unit root tests – Levin-Lin-Chu (2002), Harris-Tzavalis (1999), and Im-Pesaran-Shin (2003). All tests indicated that the VAT Gap and explanatory variables included in the specifications are stationary. The tests showed that unemployment is non-stationary and cannot be included in levels in the equation regressing the VAT Gap denoted as a percent of the VTTL. In addition to unit root tests, all model specifications were tested for cointegration using the Pedroni panel-data test (Pedroni, 1999) and the Wald test for groupwise heteroskedasticity. The residuals of all model specifications appeared to be homoscedastic, stationary, and  $I(0)$ .

## GETTING IN TOUCH WITH THE EU

### In person

All over the European Union there are hundreds of Europe Direct information centres. You can find the address of the centre nearest you at: [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en)

### On the phone or by email

Europe Direct is a service that answers your questions about the European Union. You can contact this service:

- by freephone: 00 800 6 7 8 9 10 11 (certain operators may charge for these calls),
- at the following standard number: +32 22999696 or
- by email via: [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en)

## FINDING INFORMATION ABOUT THE EU

### Online

Information about the European Union in all the official languages of the EU is available on the Europa website at: [https://europa.eu/european-union/index\\_en](https://europa.eu/european-union/index_en)

### EU publications

You can download or order free and priced EU publications at: <https://publications.europa.eu/en/publications>. Multiple copies of free publications may be obtained by contacting Europe Direct or your local information centre (see [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en)).

### EU law and related documents

For access to legal information from the EU, including all EU law since 1952 in all the official language versions, go to EUR-Lex at: <http://eur-lex.europa.eu>

### Open data from the EU

The EU Open Data Portal (<http://data.europa.eu/euodp/en>) provides access to datasets from the EU. Data can be downloaded and reused for free, for both commercial and non-commercial purposes.
